and three genes from Enterococcus faecalis V583 were predicted to encode homologs of the β-ketoacyl-acyl carrier protein synthases I or II or III of Escherichia coli (FabB or FabF, or FabH) were identified in the genomic database. The protein products were expressed, purified, and biochemically characterized. elFabH and hFabH carried out the initial condensation reaction of fatty acid biosynthesis with acetyl-Coenzyme A as a primer, and hFabB and elFabF1 carried out the elongation condensation reaction of fatty acid biosynthesis with myristoyl-ACP.

Dermatan sulfate (DS) was isolated from eel skin (Anguilla japonica) by actinase and endonuclease digestions followed by β-elimination reaction and DEAE-Sephasel chromatography. DS was a major glycosaminoglycan in eel skin with 88% of the total uronic acid. The content of IdoA2Sα1→4GalNAc4S sequence in eel skin, which is known to be a binding site to heparin cofactor II, was twice times higher than that of dermatan sulfate from porcine skin. The anti-IIα activity of eel skin dermatan sulfate mediated through heparin cofactor II (HClI) was 25 units/mg, whereas DS from porcine skin shows 23.2 units/mg. The average molecular weight was determined as 14 kDa by gel chromatography on a TSKgel G3000SWXL column. Based on H1 NMR spectroscopy, we suggest that 3-sulfated and/or 2,3-sulfated IdoA residues are present in the chain.

Induction of apoptosis in human promyelocytic leukaemia HL-60 cells by manassatin B involves release of cytochrome c and activation of caspases

Seo Borim1, Lee Kyungtae

College of Pharmacy, Kyung Hee University, Seoul 130-701.

Manassantin B classified into diterpene has been isolated from Saururus chinensis Manassantin B was found to induce apoptosis in human promyelocytic leukaemia HL-60 cells with characteristic apoptotic features like increase of nucleosomal ladder, apoptotic body formation, flipping of membrane phosphatidylinerine. Manassantin B induced FAS and FAS ligand expression, and activated caspase 8 which cleaved bid to tbid in cytosol. The release of cytochrome c to cytosol was accompanied with decrease of bcl-2 protein and increase of tbid and bax protein in mitochondria. Released cytochrome c activated caspase 9 and -3, but these effects were completely attenuated by the treatment of broad caspase inhibitor, Z-VAD-fmk. These results indicate that manassantin B induce apoptosis through upregulation of FAS, caspase family and mitochondria-related proteins.
