Fully and partially grown hexagonal boron nitride (h-BN) on Cu foil, synthesized by chemical vapor deposition method, was studied using Raman and SEM measurements. Fully and partially grown samples were successfully made from borane-ammonia complex to controlling pressure and growth time. The fully grown h-BN and partially grown h-BN exhibits a ~1,370 cm⁻¹ B-N vibrational mode (E₂g). Especially, well-aligned triangular h-BN monolayer was observed on some domain of Cu foil using SEM measurements.
