Plasma membrane calcium ATPase

Reactive oxygen species

**ABSTRACT** Intracellular  $\text{Ca}^{2+}$  mobilization is closely linked with the initiation of salivary secretion in parotid acinar cells. Reactive oxygen species (ROS) are known to be related to a variety of oxidative stress-induced cellular disorders and believed to be involved in salivary impairments. In this study, we investigated the underlying mechanism of hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) on cytosolic  $\text{Ca}^{2+}$  accumulation in mouse parotid acinar cells. Intracellular  $\text{Ca}^{2+}$  levels were slowly elevated when 1 mM  $\text{H}_2\text{O}_2$  was perfused in the presence of normal extracellular  $\text{Ca}^{2+}$ . In a  $\text{Ca}^{2+}$ -free medium, 1 mM  $\text{H}_2\text{O}_2$  still enhanced the intracellular  $\text{Ca}^{2+}$  level.  $\text{Ca}^{2+}$  entry tested using manganese quenching technique was not affected by perfusion of 1 mM  $\text{H}_2\text{O}_2$ . On the other hand, 10 mM  $\text{H}_2\text{O}_2$  induced more rapid  $\text{Ca}^{2+}$  accumulation and facilitated  $\text{Ca}^{2+}$  entry from extracellular fluid.  $\text{Ca}^{2+}$  refill into intracellular  $\text{Ca}^{2+}$  store and inositol 1,4,5-trisphosphate (1  $\mu\text{M}$ )-induced  $\text{Ca}^{2+}$  release from  $\text{Ca}^{2+}$  store was not affected by 1 mM  $\text{H}_2\text{O}_2$  in permeabilized cells.  $\text{Ca}^{2+}$  efflux through plasma membrane  $\text{Ca}^{2+}$ -ATPase (PMCA) was markedly blocked by 1 mM  $\text{H}_2\text{O}_2$  in thapsigargin-treated intact acinar cells. Antioxidants, either catalase or dithiothreitol, completely protected  $\text{H}_2\text{O}_2$ -induced  $\text{Ca}^{2+}$  accumulation through PMCA inactivation. From the above results, we suggest that excessive production of  $\text{H}_2\text{O}_2$  under pathological conditions may lead to cytosolic  $\text{Ca}^{2+}$  accumulation and that the primary mechanism of  $\text{H}_2\text{O}_2$ -induced  $\text{Ca}^{2+}$  accumulation is likely to inhibit  $\text{Ca}^{2+}$  efflux through PMCA rather than mobilize  $\text{Ca}^{2+}$  ions from extracellular medium or intracellular stores in mouse parotid acinar cells.

## INTRODUCTION

In the salivary gland, agonist-induced  $\text{Ca}^{2+}$  mobilization is the initial cellular event for fluid and amylase secretions [1]. Cytosolic  $\text{Ca}^{2+}$  can be mobilized from both external fluid and internal stores, and then rapidly eliminated to internal store and external space in parotid acinar cells [2]. It has been reported that oxidative stress is involved in salivary dysfunction caused by drugs and irradiation [3]. Reduction of submandibular saliva secretion has been observed in the rat treated with lead acetate, which induces oxidative stress [4]. Irradiation-induced hypofunction of the salivary glands has been believed to be involved with oxidative stress

[5]. Furthermore, antioxidants have a protective effect on oxidative stress-induced salivary dysfunctions [6,7]. The impairment of salivary secretion in Sjogren's syndrome, an autoimmune disease which progressively destroys salivary glands, has been known to be generated by oxidative stress and be related to intracellular  $\text{Ca}^{2+}$  accumulation in parotid acinar cells [8,9].

Although reactive oxygen species (ROS) are normally generated from partial reduction of oxygen during the aerobic respiration, they cause oxidative damage to various biological molecules, thereby disrupting normal cellular function and integrity [10,11]. The superoxide ( $\text{O}_2^{\cdot-}$ ), hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) and hydroxyl radical ( $\text{OH}^{\cdot}$ ) are considered as primary ROS which interact with

**Author contributions:** M.J.K., K.J.C. and M.N.Y. acquired and analyzed the data. M.J.K. drafted the manuscript. S.H.O., D.K.K. and S.H.K. contributed to conception and design of study. H.S.P. coordinated the study and reviewed the manuscript.

ion transporters in surface and internal membrane [12,13]. ROS are controlled by intracellular antioxidant enzymes and free radical scavengers which protect cells from oxidative stress under physiological conditions [14]. However, the imbalanced states by excessive production of ROS or reduction of antioxidants leading to morphological and functional damage of cells [15]. Although hydrogen peroxide-induced oxidative stress are correlated with overloaded intracellular  $\text{Ca}^{2+}$  levels, the mechanism of sustained  $\text{Ca}^{2+}$  overload has still been unclear due to cell-to-cell difference in  $\text{Ca}^{2+}$  transport molecules as shown by the following evidence: 1) The enhanced  $\text{Ca}^{2+}$  release from intracellular store [16-18], 2) The stimulated  $\text{Ca}^{2+}$  entry from extracellular medium [19-22] and 3) The attenuated  $\text{Ca}^{2+}$  efflux by inactivation of plasma membrane  $\text{Ca}^{2+}$ -ATPase (PMCA) or sarco/endoplasmic reticulum  $\text{Ca}^{2+}$ -ATPase (SERCA) [23-25] in various cell types. In the present study, we have therefore characterized the effect of hydrogen peroxide on intracellular  $\text{Ca}^{2+}$  signals and the underlying mechanism of  $\text{Ca}^{2+}$  accumulation in mouse parotid acinar cells. Here we report that hydrogen peroxide could accumulate intracellular  $\text{Ca}^{2+}$  by reducing  $\text{Ca}^{2+}$  efflux through PMCA, rather than by enhancing  $\text{Ca}^{2+}$  mobilization from extracellular fluid or intracellular store in pathological conditions.

## METHODS

### Materials

Collagenase P was purchased from Roche Diagnostics GmbH (Mannheim, Germany), fura-2/AM and magfura-2/AM were from Thermo Fisher Scientific (Waltham, MA, USA), inositol 1,4,5-trisphosphate ( $\text{InsP}_3$ ) was from Enzo Life Sciences (Farmingdale, NY, USA) and thapsigargin (TG) was from Tocris (Avonmouth, BS, UK). All other materials were purchased from Sigma-Aldrich (St. Louis, MO, USA).

### Isolation of parotid acinar cells

Small cluster of parotid acinar cells (8-15 cells per experiment) were freshly isolated by collagenase digestion as described previously [26]. Briefly, the parotid gland was removed from male Balb/c mice (8-10 weeks) after  $\text{CO}_2$  asphyxiation and cervical dislocation. The tissues were enzymatically digested with collagenase P in HEPES-buffered physiological saline for 30 min following gentle agitation. After isolation, parotid acinar cells were suspended in HEPES-buffered physiological saline containing 137 mM NaCl, 4.7 mM KCl, 0.56 mM  $\text{MgCl}_2$ , 1 mM  $\text{Na}_2\text{HPO}_4$ , 1.28 mM  $\text{CaCl}_2$ , 10 mM HEPES and 5.5 mM glucose (pH 7.4) until ready for use. To ensure examination in a  $\text{Ca}^{2+}$ -free condition, HEPES-buffered physiological saline containing no added  $\text{Ca}^{2+}$  was replaced with 5 mM ethylene glycol-bis (2-aminoethylether)-N,N,N',N'-tetra acetic acid (EGTA). All experimental procedures

were performed in accordance with the Guideline for the Care and Use of Laboratory Animal provided by NIH. All experiments adhered to Konyang University policies regarding the care and use of animals.

### Intracellular $\text{Ca}^{2+}$ measurements

The isolated parotid acinar cells were loaded with 5  $\mu\text{M}$  Fura-2/AM for 1 h at room temperature for measurements of intracellular  $\text{Ca}^{2+}$ . Fura-2/AM loaded cells were mounted on cover glass in the perfusion chambers. Acinar cells were continuously perfused with HEPES-buffered physiological saline. The perfusion rate (1 ml/min) was controlled using an electronic perfusion system (Warner Instrument, CT, USA). Intracellular  $\text{Ca}^{2+}$  imaging was conducted using a TILL Photonics imaging system. Fura-2/AM loaded cells were excited alternately with light at 340 nm and 380 nm using a Polychrome V monochromator (TILL Photonics, CA, USA). Fluorescence images emitted at 510 nm were captured using a Cool-SNAP HQ<sub>2</sub> camera (Photometrics, AZ, USA) attached to inverted microscope (Olympus Corp., Tokyo, JP).

### $\text{Mn}^{2+}$ quenching study to measurement of $\text{Ca}^{2+}$ entry

Fura-2 is known to have a high affinity with  $\text{Mn}^{2+}$ , and thereby fura-2 fluorescence is easily quenched by binding to  $\text{Mn}^{2+}$ . Therefore, we used this property of  $\text{Mn}^{2+}$  to quench fura-2 fluorescence as an indicator of  $\text{Ca}^{2+}$  influx through plasma membrane. Fura-2/AM loaded cells were perfused with HEPES-buffered physiological saline. The perfusion solution was then switched to 1 mM  $\text{Mn}^{2+}$ -containing solution without EGTA or  $\text{Ca}^{2+}$  for 10 min to observe the extent of  $\text{Mn}^{2+}$  entry. Fura-2/AM loaded cells were excited with light at 360 nm, a wavelength insensitive to intracellular  $\text{Ca}^{2+}$  changes. Fluorescence images emitted at 510 nm were captured.  $\text{Mn}^{2+}$  quenching the fluorescence signal was normalized using values determined by treatment of 20  $\mu\text{M}$   $\beta$ -escin to permeabilize cell membrane at the end of the experiments.

### Luminal $\text{Ca}^{2+}$ measurements in endoplasmic reticulum

The isolated acinar cells were loaded with 3  $\mu\text{M}$  magfura-2/AM for 1 h at room temperature and then attached on cover glass in the perfusion chambers. Cells were permeabilized by perfusion with 20  $\mu\text{M}$   $\beta$ -escin for 2 min in intracellular medium (ICM) containing 19 mM NaCl, 125 mM KCl, 10 mM HEPES and 1 mM EGTA (pH 7.3) as described previously [27]. To remove intracellular dye, the permeabilized cells were washed with ICM no containing  $\beta$ -escin for 15 min. Intracellular  $\text{Ca}^{2+}$  stores were subsequently refilled with  $\text{Ca}^{2+}$  by activation of SERCA. To activate SERCA, cells were perfused with ICM containing 0.650  $\mu\text{M}$   $\text{CaCl}_2$  (free  $\text{Ca}^{2+}$ =200 nM), 3 mM  $\text{Na}_2\text{ATP}$  and 1.4 mM  $\text{MgCl}_2$ . After the stores were refilled with  $\text{Ca}^{2+}$ , SERCA activity was effectively

inactivated by removal of Mg<sup>2+</sup> from ICM. The free Ca<sup>2+</sup> was constantly maintained at 200 nM throughout all experiments. Fluorescence images emitted 505 nm were captured following alternate excitation at 340 nm and 380 nm using a TILL Photonics imaging system.

## Statistical analysis

All results were presented as mean±S.E. Data were analyzed using the Student's *t* test. Differences were considered significant when the *p* value was less than 0.05. Ca<sup>2+</sup> refill rates and Ca<sup>2+</sup> release rates were estimated by fitting the changing fluorescence to a single exponential function. Relative Ca<sup>2+</sup> entry and efflux were normalized to maximum value in each experiments using Origin program.

## RESULTS

### Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>)-induced intracellular Ca<sup>2+</sup> accumulation

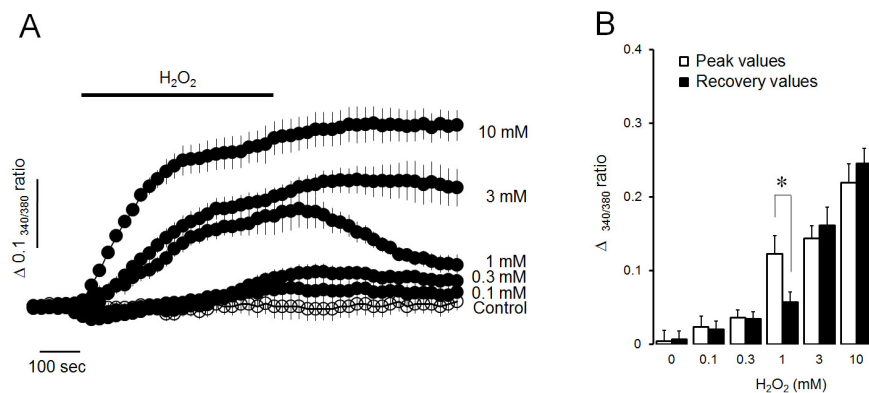

Initial experiments were performed to investigate the effect of H<sub>2</sub>O<sub>2</sub> on the intracellular Ca<sup>2+</sup> level in parotid acinar cells. The change of intracellular Ca<sup>2+</sup> concentration was monitored in various concentrations of H<sub>2</sub>O<sub>2</sub> (0.1-10 mM) in the presence of 1.28 mM extracellular Ca<sup>2+</sup> in intact cells. As shown in Fig. 1A, the perfusion of H<sub>2</sub>O<sub>2</sub> for 10 min resulted in slow increases of intracellular Ca<sup>2+</sup> concentrations. The significant Ca<sup>2+</sup> elevations were observed from 1 mM of H<sub>2</sub>O<sub>2</sub> and more rapid Ca<sup>2+</sup> accumulation was observed in 10 mM H<sub>2</sub>O<sub>2</sub>. After the cessation of H<sub>2</sub>O<sub>2</sub> perfusion, the augmented Ca<sup>2+</sup> was nearly returned to baseline at 1 mM

of H<sub>2</sub>O<sub>2</sub>. Contrastively, the sustained Ca<sup>2+</sup> increase was observed at 3 mM and 10 mM of H<sub>2</sub>O<sub>2</sub>, even if H<sub>2</sub>O<sub>2</sub> was removed from the perfusate (Fig. 1B). These results suggest that H<sub>2</sub>O<sub>2</sub> could remarkably accumulate in intracellular Ca<sup>2+</sup> and that an excess dose of H<sub>2</sub>O<sub>2</sub> could irreversibly alter Ca<sup>2+</sup> homeostasis in parotid acinar cells.

### Effects of H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> entry from extracellular medium

Next, we compared the intracellular Ca<sup>2+</sup> accumulation in the presence and the absence of extracellular Ca<sup>2+</sup> to confirm whether H<sub>2</sub>O<sub>2</sub> could facilitate Ca<sup>2+</sup> entry from the extracellular medium. Intracellular Ca<sup>2+</sup> accumulation steadily increased during treatment of H<sub>2</sub>O<sub>2</sub> in both normal Ca<sup>2+</sup> and Ca<sup>2+</sup>-free mediums (Fig. 2A). Although, a slight difference was detected in initial values of Ca<sup>2+</sup> accumulation, the final values of Ca<sup>2+</sup> accumulation showed no difference as shown in Fig. 2B (values at 300 s; 0.064±0.012 Δ ratio vs 0.034±0.007 Δ ratio, values at 600 s; 0.123±0.023 Δ ratio vs 0.122±0.015 Δ ratio, presence and absence of extracellular Ca<sup>2+</sup>, respectively). Thus, the entire Ca<sup>2+</sup> accumulation was observed regardless of external Ca<sup>2+</sup> existence.

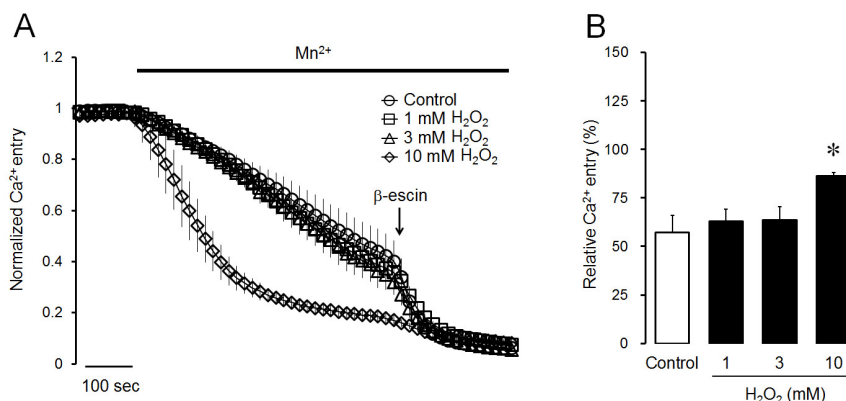

In another experiment, the Mn<sup>2+</sup> quenching test was performed to confirm Ca<sup>2+</sup> entry. As shown in Fig. 3A, the perfusion of 1 mM and 3 mM H<sub>2</sub>O<sub>2</sub> for 10 min failed to facilitate quenching of fura-2 fluorescence, whereas 10 mM H<sub>2</sub>O<sub>2</sub> markedly accelerated quenching of fura-2 fluorescence. The relative Ca<sup>2+</sup> entries at the end of the experiments were 57.14±8.73%, 62.99±6.03%, 63.56±6.79% and 86.21±1.77% in control, 1 mM, 3 mM and 10 mM H<sub>2</sub>O<sub>2</sub>-treated groups, respectively (Fig. 3B). These data indicate that the primary origin of accumulated Ca<sup>2+</sup> induced by 1 mM H<sub>2</sub>O<sub>2</sub> may not come from extracellular fluid because Ca<sup>2+</sup>

**Fig. 1. Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) produced intracellular Ca<sup>2+</sup> accumulation in intact parotid acinar cells.** (A) Effects of various concentrations (0.1-10 mM) of H<sub>2</sub>O<sub>2</sub> (filled circles) for 10 min on Ca<sup>2+</sup> accumulation in the presence of normal extracellular Ca<sup>2+</sup>. (B) The peak (open bars) and recovery (filled bars) values of intracellular Ca<sup>2+</sup> accumulation after 10 min of the perfusion and the removal of H<sub>2</sub>O<sub>2</sub>. The changes of the 340/380 ratio were expressed as means±SE obtained from at least seven separate experiments. The perfusion of H<sub>2</sub>O<sub>2</sub> resulted in slow increases of intracellular Ca<sup>2+</sup> concentrations. H<sub>2</sub>O<sub>2</sub> at concentration of 1 mM effectively accumulate intracellular Ca<sup>2+</sup> and nearly recovered to baseline after withdraw of H<sub>2</sub>O<sub>2</sub>. The sustained Ca<sup>2+</sup> increase was still observed at higher concentration over 3 mM of H<sub>2</sub>O<sub>2</sub> even if H<sub>2</sub>O<sub>2</sub> was removed from the perfusate. The relatively rapid Ca<sup>2+</sup> accumulation was observed in 10 mM H<sub>2</sub>O<sub>2</sub>. Asterisk indicates the recovery value obtained at 10 min after termination of H<sub>2</sub>O<sub>2</sub> treatment is significantly different from the peak value obtained during H<sub>2</sub>O<sub>2</sub> treatment (*p*<0.05).

**Fig. 2. H<sub>2</sub>O<sub>2</sub> still enhanced Ca<sup>2+</sup> accumulation in the absence of extracellular Ca<sup>2+</sup> in intact parotid acinar cells.** (A) Effects of 1 mM H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> accumulation in the absence (open circles) or the presence (filled circles) of normal extracellular Ca<sup>2+</sup>. (B) Intracellular Ca<sup>2+</sup> accumulation at 300 s and 600 s after perfusion of 1 mM H<sub>2</sub>O<sub>2</sub> in the absence (open bars) or the presence (filled bars) of normal extracellular Ca<sup>2+</sup>. The values were expressed as means±SE obtained from seven (control) and five (H<sub>2</sub>O<sub>2</sub>) experiments. Although a slight difference was detected in initial values of Ca<sup>2+</sup> accumulation at 300 s, the entire Ca<sup>2+</sup> accumulation at 600 s was no difference. Asterisk indicates the value obtained in Ca<sup>2+</sup>-free buffer is significantly different from the corresponding value obtained in normal Ca<sup>2+</sup> buffer ( $p < 0.05$ ).

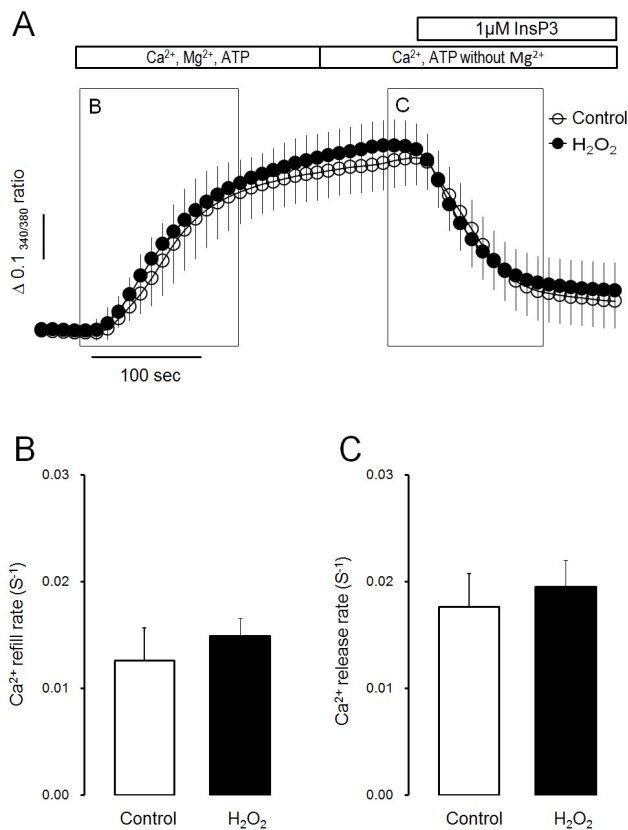

**Fig. 3. Effects of H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> entry using Mn<sup>2+</sup> quenching test in intact parotid acinar cells.** (A) Effects of various concentrations (1-10 mM) of H<sub>2</sub>O<sub>2</sub> for 10 min on normalized Ca<sup>2+</sup> entry. (B) Effects of H<sub>2</sub>O<sub>2</sub> on relative Ca<sup>2+</sup> entry at the end of experiments. The values were expressed as means±SE obtained from at least six separate experiments. H<sub>2</sub>O<sub>2</sub> at the concentration of 1 mM (open squares) and 3 mM (open triangles) failed to facilitate Ca<sup>2+</sup> entry, whereas 10 mM H<sub>2</sub>O<sub>2</sub> (open diamonds) remarkably accelerated Ca<sup>2+</sup> entry through plasma membrane. Asterisk indicates the value obtained in H<sub>2</sub>O<sub>2</sub>-treated experiments (filled bars) is significantly different from the corresponding value obtained in control experiments (open bar) ( $p < 0.05$ ).

accumulation was still observed in Ca<sup>2+</sup>-free solution and Mn<sup>2+</sup> quenching of fura-2 fluorescence was not facilitated in the presence of 1 mM H<sub>2</sub>O<sub>2</sub>. Therefore, we used a concentration of 1 mM H<sub>2</sub>O<sub>2</sub> in the following experiments to identify the primary mechanism of Ca<sup>2+</sup> accumulation. The next experiment was planned to evaluate whether H<sub>2</sub>O<sub>2</sub> can influence Ca<sup>2+</sup> transport through intracellular Ca<sup>2+</sup> stores membrane.

### Effects of H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> transport through intracellular Ca<sup>2+</sup> stores membrane

To determine the influence of H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> transport through endoplasmic reticulum (ER) membrane, we employed unidirectional fluorescent ER Ca<sup>2+</sup> measurements in permeabilized cells. Parotid acinar cells were loaded with a low-affinity Ca<sup>2+</sup> dye

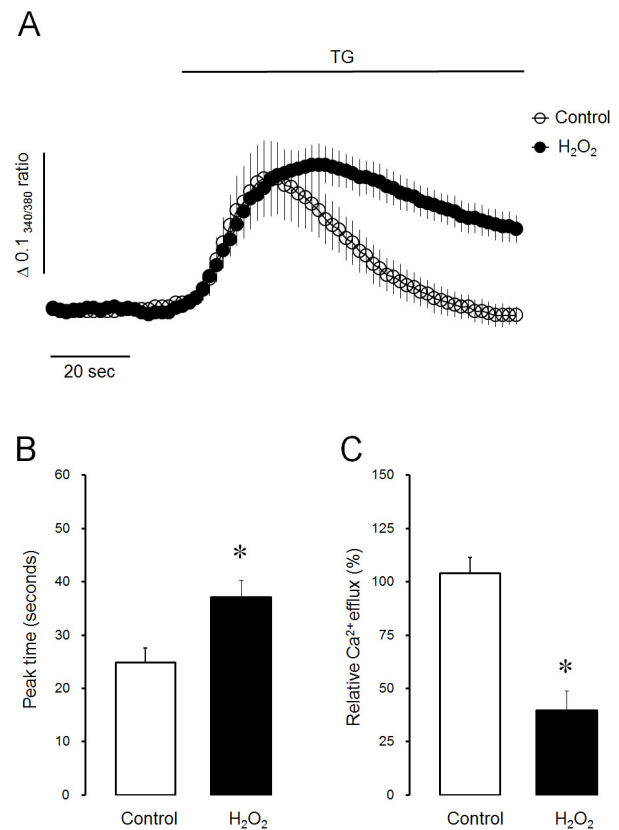

magfura-2/AM and then permeabilized with β-escin to release the cytosolic dye. As shown in Fig. 4A, the perfusion with intracellular medium containing CaCl<sub>2</sub>, MgCl<sub>2</sub> and ATP resulted in an increase of the fluorescence ratio that indicates an effective Ca<sup>2+</sup> refill into the ER stores. In these conditions, the perfusion of 1 mM H<sub>2</sub>O<sub>2</sub> failed to change Ca<sup>2+</sup> refill rate into the ER stores (Fig. 4B). After the stores were refilled with Ca<sup>2+</sup>, MgCl<sub>2</sub> was eliminated from the buffer to provide SERCA inactivation. Application of 1 μM InsP<sub>3</sub> caused significant Ca<sup>2+</sup> release from the stores, but H<sub>2</sub>O<sub>2</sub> had no effect on InsP<sub>3</sub>-induced Ca<sup>2+</sup> release rates (Fig. 4C). These findings indicate that 1 mM H<sub>2</sub>O<sub>2</sub> led to neither Ca<sup>2+</sup> refill nor InsP<sub>3</sub>-induced Ca<sup>2+</sup> release through the ER membrane.

**Fig. 4. H<sub>2</sub>O<sub>2</sub> failed to modulate Ca<sup>2+</sup> transport through endoplasmic reticulum (ER) membrane in permeabilized parotid acinar cells.** (A) The effect of H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> refill and InsP<sub>3</sub>-induced Ca<sup>2+</sup> release through ER membrane in permeabilized cells. (B) The effect of H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> refill rates into intracellular Ca<sup>2+</sup> stores. (C) The effect of H<sub>2</sub>O<sub>2</sub> on InsP<sub>3</sub>-induced Ca<sup>2+</sup> release from Ca<sup>2+</sup> stores. The values were expressed as means±SE obtained from five (control) and six (H<sub>2</sub>O<sub>2</sub>) experiments. ER Ca<sup>2+</sup> stores were loaded with the buffer containing MgCl<sub>2</sub>, Na<sub>2</sub>ATP and CaCl<sub>2</sub>. After Ca<sup>2+</sup> loading, MgCl<sub>2</sub> was eliminated to SERCA inactivation at 60 s prior to 1 μM InsP<sub>3</sub> application (open circles and bars). The same procedure was repeated in H<sub>2</sub>O<sub>2</sub>-treated permeabilized cells (filled circles and bars). The perfusion of H<sub>2</sub>O<sub>2</sub> resulted in change neither Ca<sup>2+</sup> refill rate nor InsP<sub>3</sub>-induced Ca<sup>2+</sup> release rate through ER membrane in permeabilized cells.

### H<sub>2</sub>O<sub>2</sub> inhibits Ca<sup>2+</sup> efflux through PMCA inactivation

To confirm the effect of H<sub>2</sub>O<sub>2</sub> on PMCA activity, we evaluated the effect of H<sub>2</sub>O<sub>2</sub> in Ca<sup>2+</sup>-free conditions during the depletion of Ca<sup>2+</sup> from the ER store by the treatment of 1 μM TG, a SERCA blocker. As shown in Fig. 5A, TG induced a transient Ca<sup>2+</sup> elevation that indicates spontaneous Ca<sup>2+</sup> release from the ER stores, and these responses were completely returned to baseline, which means there was Ca<sup>2+</sup> efflux by plasma membrane Ca<sup>2+</sup>-ATPase (PMCA) in control experiments. When H<sub>2</sub>O<sub>2</sub> was treated with TG, the peak time of Ca<sup>2+</sup> elevation was delayed (Fig. 5B, control; 24.83±2.76 s vs. H<sub>2</sub>O<sub>2</sub>; 37.17±3.17 s) and Ca<sup>2+</sup> efflux was not fully returned to the control value in 1 mM H<sub>2</sub>O<sub>2</sub>-treated group (Fig. 5C, control; 103.95±7.62% vs. H<sub>2</sub>O<sub>2</sub>; 39.58±9.33%).

**Fig. 5. H<sub>2</sub>O<sub>2</sub> attenuated Ca<sup>2+</sup> efflux in thapsigargin (TG)-treated intact acinar cells.** (A) The effect of H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> efflux during the depletion of ER Ca<sup>2+</sup> store by TG treatment in Ca<sup>2+</sup>-free buffer. (B) The effect of H<sub>2</sub>O<sub>2</sub> on the peak time of intracellular Ca<sup>2+</sup> elevation. (C) The effect of H<sub>2</sub>O<sub>2</sub> on the relative Ca<sup>2+</sup> efflux at the end of experiments. The values were expressed as means±SE obtained from seven (control) and five (H<sub>2</sub>O<sub>2</sub>) experiments. When H<sub>2</sub>O<sub>2</sub> was treated with TG (filled circles and bars), the Ca<sup>2+</sup> elevation was delayed and Ca<sup>2+</sup> efflux was not fully recovered to baseline compared with control values (open circles and bars). Asterisks indicate the value obtained in H<sub>2</sub>O<sub>2</sub>-treated experiments is significantly different from the corresponding value obtained in control experiments (p<0.05).

To further test the effect of H<sub>2</sub>O<sub>2</sub> on PMCA activity in another set of experiments, Ca<sup>2+</sup> store were initially depleted with 1 μM TG, and then Ca<sup>2+</sup> entry and Ca<sup>2+</sup> efflux was fully stimulated by adding and removing extracellular 1.28 mM Ca<sup>2+</sup> in intact cells, respectively. In the control experiment, as shown in Fig. 6A, the addition of extracellular Ca<sup>2+</sup> remarkably stimulated Ca<sup>2+</sup> entry, and the elimination of extracellular Ca<sup>2+</sup> resulted in a clear extrusion of intracellular Ca<sup>2+</sup> to external space. In 1 mM H<sub>2</sub>O<sub>2</sub>-treated cells, the elevated intracellular Ca<sup>2+</sup> level was not returned to baseline by withdrawal of extracellular Ca<sup>2+</sup>. That means the extrusion of intracellular Ca<sup>2+</sup> was markedly disrupted by treatment of 1 mM H<sub>2</sub>O<sub>2</sub>. Additionally, the perfusion of antioxidants with H<sub>2</sub>O<sub>2</sub>, either 30 μg/ml catalase or 2 mM dithiothreitol, completely protected the diminished Ca<sup>2+</sup> efflux in TG-treated intact acinar cells (Fig. 6B). These evidences suggest that H<sub>2</sub>O<sub>2</sub> may induce Ca<sup>2+</sup> accumulation by inhibition of PMCA activity in mouse parotid

**Fig. 6.  $H_2O_2$  suppressed  $Ca^{2+}$  efflux through PMCA in intact parotid acinar cells.** (A) The effect of  $H_2O_2$  and antioxidants on  $Ca^{2+}$  efflux through PMCA. (B) The effect of  $H_2O_2$  and antioxidants on relative  $Ca^{2+}$  efflux at the end of experiments. The values were expressed as means $\pm$ SE obtained from at least five separate experiments.  $Ca^{2+}$  store were initially depleted with 1  $\mu$ M TG, and then  $Ca^{2+}$  entry and  $Ca^{2+}$  efflux was fully stimulated by adding and removing extracellular 1.28 mM  $Ca^{2+}$ . Application of  $H_2O_2$  (filled circles and bar) resulted in remarkable inhibition of  $Ca^{2+}$  efflux through PMCA compared with control values (open circles and bar) in TG-treated acinar cells. The antioxidants, 30  $\mu$ g/ml catalase (filled triangles and gray bar) or 2 mM dithiothreitol (DTT, filled diamonds and gray bar), completely protected these diminished  $Ca^{2+}$  efflux by  $H_2O_2$  in TG-treated intact acinar cells. Asterisk indicates the value obtained in  $H_2O_2$ -treated experiments is significantly different from the corresponding value obtained in control experiments ( $p < 0.05$ ).

acinar cells.

## DISCUSSION

The present study provides evidence that the reactive oxygen species  $H_2O_2$  accumulates cytosolic  $Ca^{2+}$  by attenuating  $Ca^{2+}$  efflux through PMCA rather than by mobilizing the  $Ca^{2+}$  from the extracellular space or intracellular  $Ca^{2+}$  store in mouse parotid acinar cells. Cytosolic free  $Ca^{2+}$  plays a crucial role in the salivary secretion of parotid acinar cells, and  $Ca^{2+}$  can be mobilized from both the external fluid and the internal  $Ca^{2+}$  stores such as endoplasmic reticulum, acidic store and mitochondria to elicit physiological responses [28-30]. Acetylcholine, a major agonist in the parotid gland, is known to initially mobilize  $Ca^{2+}$  from internal stores through activation of  $InsP_3$  receptors, and to subsequently activate the store-operated  $Ca^{2+}$  entry from the external medium to refill the depleted stores [31,32]. After  $Ca^{2+}$  mobilization, cytosolic  $Ca^{2+}$  was rapidly eliminated to internal store and external space by SERCA and PMCA, respectively. Since the accumulation of intracellular  $Ca^{2+}$  causes cellular toxicity, including apoptosis and necrosis, basal intracellular  $Ca^{2+}$  concentrations are finely regulated to under about 10,000 folds compare to the extracellular space [33]. The balance between  $Ca^{2+}$  mobilization and  $Ca^{2+}$  elimination are regulated by various  $Ca^{2+}$  transporters expressed both in plasma membrane and ER membrane [34]. Oxidative stress is well known risk factor which induces cellular dysfunction of several tissues and organs [10,11], and oxidants-induced cellular dysfunction are closely linked with intracellular  $Ca^{2+}$  accumulation [12,13]. In this study, when parotid acinar cells were exposed to 1 mM  $H_2O_2$  in normal  $Ca^{2+}$  buffer, there was a significant intracellular  $Ca^{2+}$  accumulation, and the elevated  $Ca^{2+}$  was

nearly returned to baseline after the cessation of  $H_2O_2$  perfusion. Generally,  $H_2O_2$  is known to accumulate cytosolic  $Ca^{2+}$  without acute cell death at concentrations from 10  $\mu$ M to 5 mM in various cell types [16-25]. Thus, mouse parotid acinar cells are thought to be relative resistance to  $H_2O_2$ .

To confirm the underlying mechanism of  $H_2O_2$ -induced  $Ca^{2+}$  accumulation, we measured  $Ca^{2+}$  transport through plasma membrane and ER membrane. Actually,  $H_2O_2$ -induced  $Ca^{2+}$  entry through plasma membrane is important for intracellular  $Ca^{2+}$  accumulation, and transient-receptor potential channels and store-operated  $Ca^{2+}$  channels are known to involved in  $Ca^{2+}$  overload in various cell types [19-22]. However, in our study, the entire  $Ca^{2+}$  accumulation induced by 1 mM  $H_2O_2$  was not suppressed by the elimination of extracellular  $Ca^{2+}$  in intact acinar cells and  $Mn^{2+}$  quenching property was not facilitated by the perfusion of 1 mM  $H_2O_2$ . Since 10 mM  $H_2O_2$  produced more rapid cytosolic  $Ca^{2+}$  elevation and accelerated  $Mn^{2+}$  quenching fura-2 fluorescence, higher concentrations of  $H_2O_2$  may be required to promote  $Ca^{2+}$  influx in parotid acinar cells. Moreover,  $H_2O_2$  failed to stimulate  $InsP_3$ -induced  $Ca^{2+}$  release for measurement  $Ca^{2+}$  transport through ER membrane in permeabilized acinar cells. These results suggest that  $H_2O_2$  could accumulate cytosolic  $Ca^{2+}$  irrelevant of  $Ca^{2+}$  entry from external fluid and  $Ca^{2+}$  release from ER stores. Since  $H_2O_2$  could mobilize  $Ca^{2+}$  from other TG-insensitive intracellular stores such as mitochondria [35,36], we evaluated the effect of  $H_2O_2$  in  $Ca^{2+}$ -free conditions after the depletion of  $Ca^{2+}$  from the ER store by the pretreatment of 1  $\mu$ M TG (Supplementary Fig. 1). TG induced a transient  $Ca^{2+}$  elevation, and these responses were completely returned to baseline. After return to baseline, the perfusion of 1 mM  $H_2O_2$  failed to increase the  $Ca^{2+}$  release. It has been proposed that mitochondrial  $Ca^{2+}$  release by  $H_2O_2$  could conceivably contribute to  $Ca^{2+}$  accumula-

tion when cytosolic Ca<sup>2+</sup> is high, since H<sub>2</sub>O<sub>2</sub> evoked cytosolic Ca<sup>2+</sup> elevation when cells were pre-stimulated by cholecystokinin (CCK) but failed to evoke cytosolic Ca<sup>2+</sup> elevation without pre-stimulation of CCK in ER Ca<sup>2+</sup> stores were depleted pancreatic acinar cells [24]. Thus, 1 mM H<sub>2</sub>O<sub>2</sub>-induced Ca<sup>2+</sup> accumulation is not due to mobilize Ca<sup>2+</sup> from other intracellular Ca<sup>2+</sup> stores or mitochondria in our study. On the other hand, when TG were treated with 1 mM H<sub>2</sub>O<sub>2</sub> in the absence of extracellular Ca<sup>2+</sup>, cytosolic Ca<sup>2+</sup> elevation was delayed and enhanced Ca<sup>2+</sup> was not fully recovered to baseline. Actually, slow intracellular Ca<sup>2+</sup> elevation by SERCA inhibition was likely due to spontaneous release or leak of Ca<sup>2+</sup> from the ER stores, and slow Ca<sup>2+</sup> decline was due to extrusion of Ca<sup>2+</sup> to the external space by PMCA or Na<sup>+</sup>/Ca<sup>2+</sup> exchanger (NCX) activation [37]. Although, NCX are also known to sensitive to oxidants [12,13], there is no evidence of the expression and the participation of NCX for Ca<sup>2+</sup> extrusion in parotid acinar cells at the present time. Furthermore, Ca<sup>2+</sup> extrusion was not affected when Na<sup>+</sup> was replaced with NMDG<sup>+</sup> to NCX inactivation in our preliminary study (data not shown). Since the removal of elevated Ca<sup>2+</sup> from cytosol to the extracellular site was carried out mainly by PMCA under inhibition of SERCA by TG treatment in parotid acinar cells, this finding strongly suggests that H<sub>2</sub>O<sub>2</sub> effectively suppressed PMCA activity. In another set of experiment, we further investigated the effect of H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> efflux through PMCA. PMCA activity was assessed by a Ca<sup>2+</sup> decrease to baseline by removing extracellular Ca<sup>2+</sup> after store-operated Ca<sup>2+</sup> entry was fully stimulated by adding extracellular Ca<sup>2+</sup> in TG-treated cells. Here we show that the extrusion of intracellular Ca<sup>2+</sup> was markedly disrupted by pretreatment of 1 mM H<sub>2</sub>O<sub>2</sub> in TG-treated intact acinar cells. Actually, the initial Ca<sup>2+</sup> levels were slightly higher in H<sub>2</sub>O<sub>2</sub>-treated cells than in control cells. These results were considered caused by blocking of Ca<sup>2+</sup> efflux through PMCA, rather than by enhancing of the Ca<sup>2+</sup> entry through activation of store-operated Ca<sup>2+</sup> channels. Furthermore, the inhibitory effects of H<sub>2</sub>O<sub>2</sub> on Ca<sup>2+</sup> efflux were strongly protected by the adding of catalase, an enzyme degrading hydrogen peroxide, and DTT, a sulfhydryl reducing agent.

In fact, it has been reported that functionally important sulfhydryl group are present within PMCA and SERCA molecules that is localized within the catalytic and controlling centers of Ca<sup>2+</sup>-ATPase [38-40]. We previously reported that H<sub>2</sub>O<sub>2</sub> accumulates intracellular Ca<sup>2+</sup> by attenuating SERCA activity in pancreatic acinar cells [25]. Interestingly, in this study, H<sub>2</sub>O<sub>2</sub> failed to change Ca<sup>2+</sup> refilling into the ER store through SERCA by the application of Ca<sup>2+</sup> and Mg-ATP in permeabilized parotid acinar cells. As shown in supplement Fig. 2, three folds higher concentration of H<sub>2</sub>O<sub>2</sub> are need to inhibit Ca<sup>2+</sup> efflux through PMCA in pancreatic acinar cells compared to parotid acinar cells. Ca<sup>2+</sup>-ATPase has distinct isoforms with different expression and regulation properties that caused diversity of Ca<sup>2+</sup> signaling in various cell types [41]. It has been known that distinct Ca<sup>2+</sup>-ATPase isoforms have different sensitivity to ROS due to locational difference of

sulfhydryl group [42-44]. Thus, the different sensitivities of Ca<sup>2+</sup>-ATPase to H<sub>2</sub>O<sub>2</sub> between parotid and pancreatic acinar cells are thought to be due to differences in expression and regulation of Ca<sup>2+</sup>-ATPase. In immunofluorescence study, PMCA1 is distributed throughout the plasma membrane, PMCA2 is localized to the basolateral membrane and PMCA4 is localized to the apical membrane in parotid acinar cell [45]. Even though PMCA are dominantly expressed in apical membrane in pancreatic acinar cells [46,47], isoform specific distributions are not clear at the present time. Although the further studies are need to elucidate this issues, we predict from the present results that H<sub>2</sub>O<sub>2</sub> could lead to accumulate cytosolic Ca<sup>2+</sup> by attenuation of Ca<sup>2+</sup> efflux through the oxidation of functional sulfhydryl groups of PMCA in parotid acinar cells.

From the above results, we concluded that H<sub>2</sub>O<sub>2</sub> can accumulate intracellular Ca<sup>2+</sup> by attenuating Ca<sup>2+</sup> efflux through PMCA, rather than by mobilizing Ca<sup>2+</sup> from extracellular medium or intracellular stores in parotid acinar cells. Thus the primary target for H<sub>2</sub>O<sub>2</sub> excessively generated in pathological conditions is considered PMCA in mouse parotid acinar cells.
